At healthy smiles at Mt Eliza we pride on investing in technology that enhances our patient care. We would like to introduce the latest addition of an operating microscope to our dental rooms.

Most dentists use dental loupes to have enlarged and clearer view of the patients' mouth. Using an operating microscope takes this to a new level as the magnification is much higher and this enables the dentist with early detection of cracked teeth, decay, gum disease and allows the dentist to treat the conditions early before the symptoms develop.

Teeth are checked under the microscope after dental cleans ensuring nothing is left to chance. The crown margins can be checked for better fit. Surgical procedures have better visibility.

With endodontic procedures of Root Canal Treatment, improved visibility enables the dentist to negotiate difficult and calcified canals and diagnose and treat cracks early. Enhanced clarity leads to less 'tooth structure loss' thus ensuring better treatment and success.

The microscope we are using is an award-winning CJ Optik Dental Microscope from Germany.

When having a dental procedure, whether it be a clean or a crown there is only so much the human eye can see. Dental Microscope allows the dentist to see what they otherwise could not with the naked eye, ensuring that the patient is getting the best dental treatment.
